

Overexpression of PKC α in Breast Cancer Cells Induces Migration Through p120-Catenin Transcriptional Downregulation

Several factors have been identified that influence epithelial-mesenchymal transition (EMT) in breast cancer cells. We previously reported that overexpression of PKC α in breast cancer predicts tamoxifen resistant secondary tumors (Tonetti, 2003). In breast cancer cells, stable overexpression of PKC α (T47D/PKC α) leads to hormone-independent growth as well as tamoxifen resistance (Chisamore, 2001). In our current study we report that PKC α overexpression increases the metastatic potential of breast cancer cells through induction of a nonclassical EMT. T47D/PKC α cells are morphologically distinct from T47D/neo cells and do not retain the cuboidal structure of epithelial breast cancer cells. Overexpression of PKC α resulted in significantly enhanced migratory capabilities in the Boyden chamber assay. PKC activation by phorbol 12-myristate 13 acetate further enhanced migration in T47D/PKC α cells. Pharmacological inhibition with the classical PKC inhibitor Go6976 reduced the migratory capacity of T47D/PKC α cells. Transient siRNA-mediated knockdown of PKC α (120 h) significantly reduced both basal and NIH3T3 fibroblast conditioned media-induced migration in T47D/PKC α cells. Levels of adherens junction proteins E-cadherin, α -E-catenin, β -catenin and p120-catenin were significantly downregulated in T47D/PKC α cells compared to T47D/neo cells as determined by western blot. Levels of E-cadherin protein were restored by more than 50% after 168 h of PKC α knockdown in T47D/PKC α cells. E-cadherin transcripts analyzed by SYBR green RT-qPCR were significantly higher in T47D/PKC α cells compared to T47D/neo control cells while there was no change in expression of β -catenin or α -E-catenin transcripts. Only p120-catenin transcript levels were significantly lower. Treatment with proteasomal inhibitor MG132 induces accumulation of E-cadherin but not p120-catenin. Taken together, these data suggest that PKC α may be responsible for EMT in breast cancer cells through upstream signaling that leads to transcriptional inhibition of p120-catenin and subsequent degradation of E-cadherin. Further PKC α expression may not only be predictive of tamoxifen-resistance but of increased potential for metastasis.
